Outline

- ▶ **Computational learning**
- ▶ **Design of W-operators**
- ▶ **Amount of data available**
- ▶ **Distribution of the domain**
- ▶ **Size of the window**
- ▶ **Constraints**
- ▶ **Gray scale and motion applications**
- ▶ **Conclusion**

Learning a concept

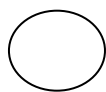

- **Domain:** planar shapes
- **concept:** color **RED**

	Red	Other
□	80	30
○	15	60

Learning a concept

Red Other

	80	30
	15	60

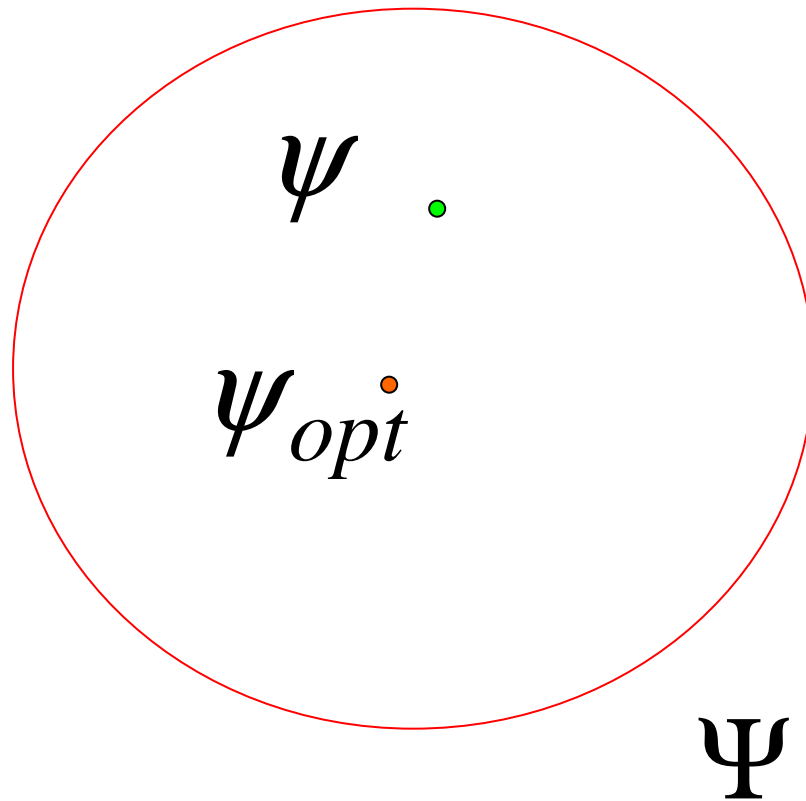

Terminology

- **domain:** objects with a random distribution
- **concept:** a set of objects of a given domain (or a binary function)
- **teacher:** he says if a generic object satisfies the concept, but he may make mistakes

Terminology

- **example:** an object classified by the teacher
- **learning algorithm:** gives an hypothesis for the concept from a collection of examples
- **training data:** examples used in the learning algorithm

The optimization problem

The optimization problem

ψ is a classifier on a random domain

$Er[\psi]$ is the error of ψ

ψ_{opt} is a classifier of minimum error

$$Er[\psi_{opt}] \leq Er[\psi], \forall \psi \in \Psi$$

Error measure

➔ Design goal is to find a function with **minimum risk**.

➔ **Risk** (expected loss) of a function :

$$R(\psi) = E[l(\psi(X), Y)]$$

X is a random set
 Y is a binary random variable

➔ **Loss** function

$$l : \{0, 1\} \times \{0, 1\} \rightarrow R^+$$

Join probability

$$R(\psi) = \sum_{X,Y} l(\psi(X), Y) p(X, Y)$$

$p(X, Y)$ needs to be estimated
from training data

MAE example

→ **Example : MAE loss function**

$$l_{MAE}(a, b) = |a - b| \quad a, b \in \{0, 1\}$$

$$MAE\langle\Psi\rangle = E[|\psi(X) - Y|]$$

→ **Optimal MAE function**

$$\psi(X) = \begin{cases} 1 & p(1, X) > p(0, X) \\ 0 & p(1, X) \leq p(0, X) \end{cases}$$

Generalization

OBSERVED

GENERALIZED

PAC learning

L is Probably Approximately Correct (PAC)

For $m > m(\varepsilon, \delta)$ examples

$$\Pr(|R(\psi) - R(\psi_{opt})| < \varepsilon) > 1 - \delta$$

$$\varepsilon, \delta \in (0, 1)$$

Efficiency

L should be computed in polynomial time

ψ should be represented in polynomial storage space

ψ should be executed in polynomial time

PAC learning procedure

1. *Estimate $P(X,Y)$ from training images*

2. *Attribute the binary label that **minimizes the loss**, for each observed shape*

3. *Make representation simplification (e.g., compute base), and attribute labels to non-observed shapes (generalization or prediction).*

Example : Boolean function minimization, where non-observed shapes may be regarded as don't cares for minimization purpose.

Representation

Window $W = 1 \times 3$

$$\mathcal{K}(\Psi) = \left\{ \begin{array}{c} \square \blacksquare \blacksquare \\ \blacksquare \square \square \\ \blacksquare \blacksquare \square \\ \blacksquare \blacksquare \blacksquare \end{array} \right\}$$

$$\mathcal{B}(\Psi) = \left\{ \begin{array}{c} [\square \blacksquare \blacksquare, \blacksquare \blacksquare \blacksquare], \\ [\blacksquare \square \square, \blacksquare \blacksquare \square], \\ [\blacksquare \blacksquare \square, \blacksquare \blacksquare \blacksquare] \end{array} \right\}$$

$X11$
 $1X0$
 $11X$

$$\psi = \lambda_{X11} \cup \lambda_{1X0} \cup \lambda_{11X}$$

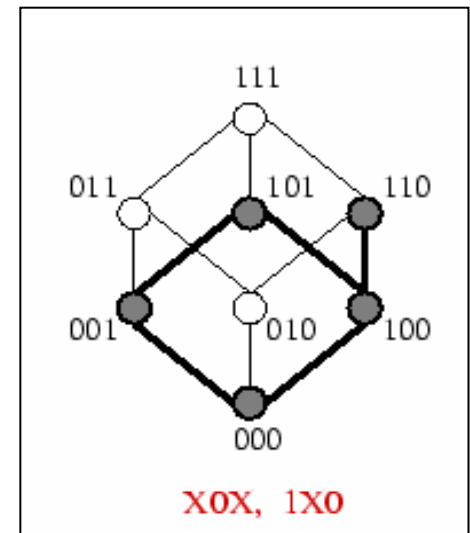

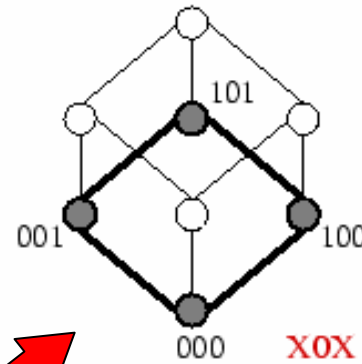

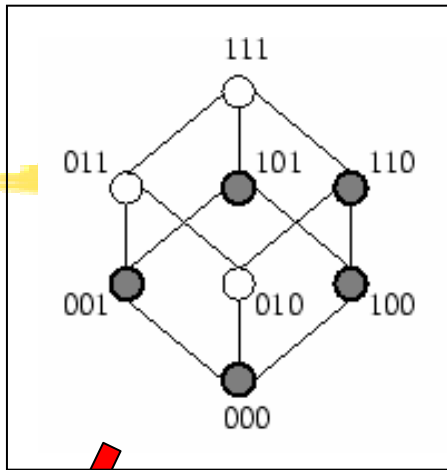

Pictorial representation

Simplified representation

dark = 1
white = 0

Minimization by Quine-McCluskey

ISI (incremental splitting of intervals)

➔ Interval : $[A, B] \subseteq \mathcal{P}(W)$

➔ Splitting of $[A, B]$ by X , $X \in [A, B]$

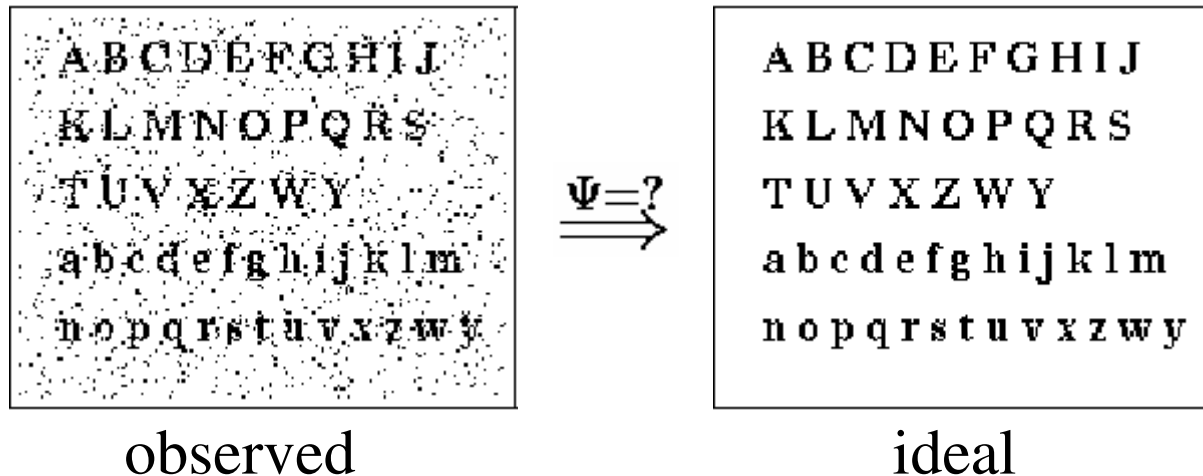

$$[A, B] \setminus X = \{[A, B \cap \{a\}^c] : a \in P \cap A^c\} \cup \{[A \cup \{b\}, B] : b \in P^c \cap B\}$$

ISI algorithm

The problem

Find an image operator that transforms the **observed** image to the respective **ideal** (or “close to the ideal”) image.

Binary image operators

➔ Binary image : $f : E \rightarrow \{0, 1\}$

➔ Binary images can be understood as sets :

$$f \longleftrightarrow S$$
$$x \in S \Leftrightarrow f(x) = 1 \quad \forall x \in E$$

$(\mathcal{P}(E), \subseteq)$ is a complete Boolean lattice

➔ Binary image operators = set operators :

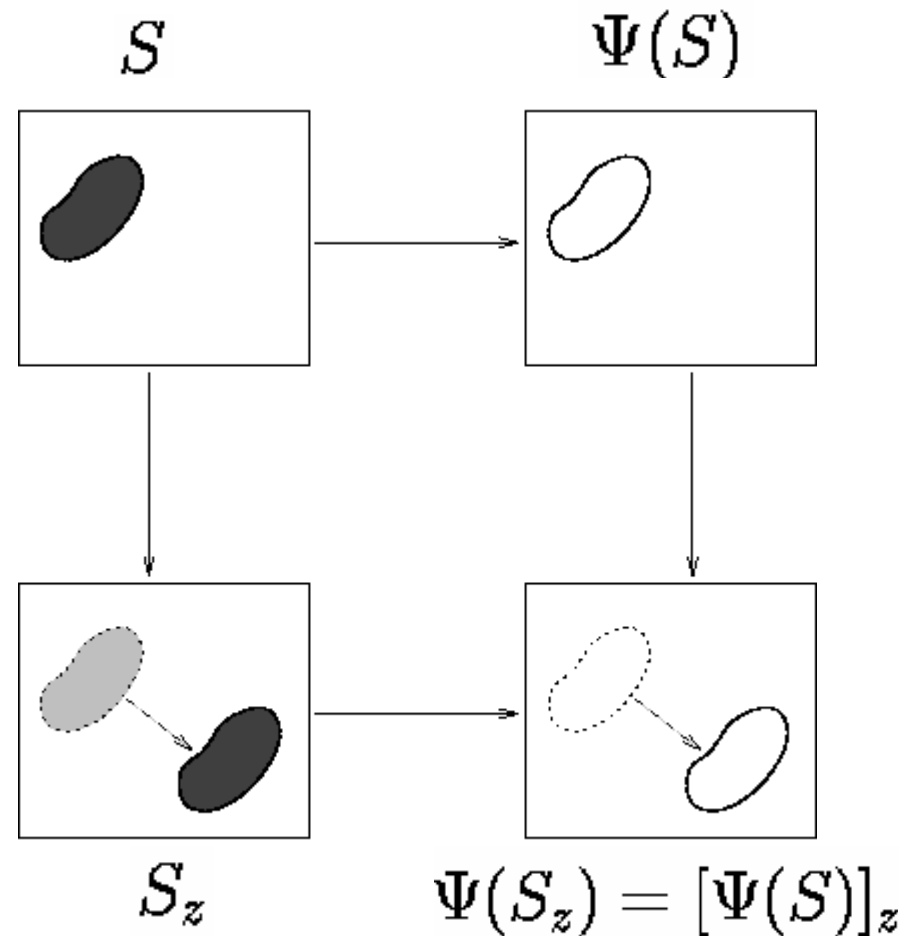

$$\Psi : \mathcal{P}(E) \rightarrow \mathcal{P}(E)$$

Translation invariance

➔ Translation of S by z :

$$S_z = \{x + z : x \in S\}$$

➔ $\Psi : \mathcal{P}(E) \rightarrow \mathcal{P}(E)$ is
translation-invariant iff
 $\Psi(S_z) = [\Psi(S)]_z$

Local definition

Window : $W \subseteq E$

➔ An image operator is **locally defined** within W iff

$$x \in \Psi(S) \iff x \in \Psi(S \cap W_x)$$

W-operators

→ { Translation invariance
+
local definition within W
=
W-operators

$$\Psi(S)(z) = \psi\left(\begin{array}{ccc} \square & \square & \square \\ \square & \square & \square \\ \square & \square & \square \end{array}\right)$$

→ W-operators are characterized by Boolean functions.

Statistical Hypothesis

X and Y are jointly stationary

$$P(S \cap W_z, Y)$$

is the same for any z in E

Difficulties

➔ The space of W -operators is VERY large.

➔ $|W| = n \implies \begin{cases} 2^{2^n} & W \text{ operators,} \\ 2^n & \text{conditional probabilities to be estimated} \end{cases}$

➔ **Consequences :**

- Large amount of data (training images) are required for a good estimation of these parameters
- Learning algorithm complexity increases

Difficulties

x1	x2	$p(-1,x1,x2)$	$p(0,x1,x2)$	$p(1,x1,x2)$	$p(x1,x2)$	y	Error

Constraints

→ Structural Constraints

- impose maximum number of elements in the basis
- use alternative structural representations (e.g., sequential)

→ Algebraic constraints

- consider class of operators satisfying a given algebraic property (e.g., increasingness, idempotence, auto-dualism, etc)

Structural Constraint : iterative design (1)

➔ **Motivation** : composition of operators over small windows produces an operator over a larger window

➔ $\Psi = \Psi_2(\Psi_1)$ is a $W \oplus W$ -operator

Iterative design procedure

➔ Successive application of the single iteration design procedure

Algebraic constraints

Design of operators based on
the **switching approach**

- estimate optimal W -operator
- **switch** value of the optimal W -operator in such a way that the resulting operator satisfies the algebraic constraint

Algebraic constraints

Increasing W -operators

$$x \leq y \Rightarrow \psi(x) \leq \psi(y)$$

increasing

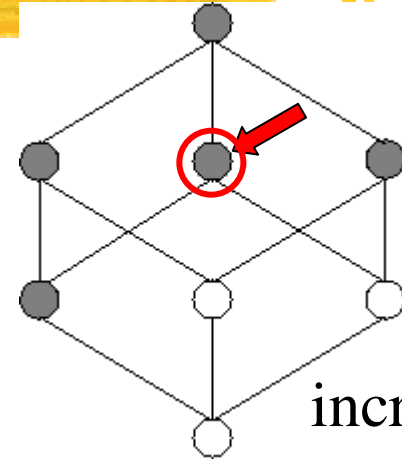

non-increasing

Switching approach

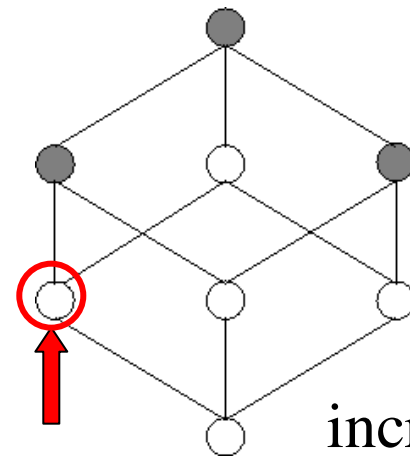

Design of increasing W -operators

non-increasing

increasing

increasing

Switching approach

Inversion set

➡ Only **inversion set** elements need to be switched.

➡ Switching may **increase risk**

➡ There exists a **switching cost** (amount of risk increase due to the switching) for each element in the inversion set.

➡ *Goal* : find switching that **minimizes overall risk increase**

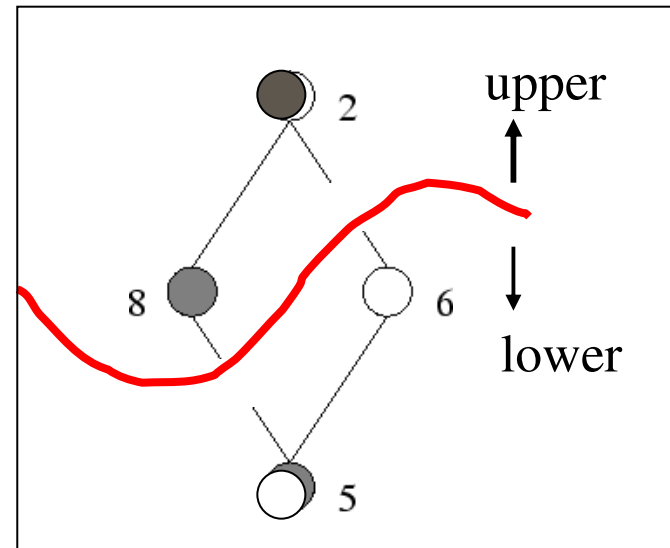

Switching → Partition

Inversion set

Gray-scale image operators

➔ Gray-scale image : $f : E \rightarrow K \quad f \in K^E$
 $K = \{0, 1, \dots, 255\}$

➔ Gray-scale image operator : $\Psi : K^E \rightarrow K^E$

➔ Characteristic function : $\psi : K^W \rightarrow K$

➔ Design of gray-scale W -operators

Same design procedure could be applied

Motion Tracking

Conclusion

- A powerful tool to solve practical problems
- Hard problems requires modeling of prior knowledge
- Prior knowledge modeling implies complex problems in Statistics, Algebra and Combinatory
